

Test Plan

Objectives

1. Verify that the search input correctly return matching listings.
2. Verify filters correctly return matching listings.
3. Validate that combinations of filters correctly intersect and don't produce invalid or unexpected results.
4. Ensure search results pagination or scroll works reliably, user can navigate through result pages without missing or duplicating listings.

In-Scope / Out-of-Scope

In-Scope

1. Search input
2. Filters: for sale, home type, price, number of beds, construction status...
3. Combination of multiple filters together
4. Pagination or scroll behavior (navigation across multiple pages of results)
5. "No results" scenarios

Out-of-Scope

1. Details page of each listing
2. User account / login / "save search" functionality
3. Advanced features
5. SEO, accessibility compliance, or internationalization
6. Integration with external APIs or third-party services

Assumptions

- The site's search feature allows filtering by at least sale, home type, price, number of beds, construction status...
- Pagination or scroll is used when there are many results
- Test environments (staging or dev) mirror production behavior with representative data
- Users might combine multiple filters; the system expects and supports such combinations without conflicts.

Risks

- Inconsistent or incomplete data: if some listings have missing data, filters might behave unpredictably.
- Performance degradation: with many listings or under heavy load, search results or pagination may be slow or time out.
- UI/UX issues: poor error handling, unresponsive filter controls.

High-Level Test Types

Manual Tests

- Exploratory testing of search UI, basic filter and search combinations, “no results” states, UI/UX and input validation.

Automated Tests

- Automation candidates: basic filter combinations, pagination navigation, scrolling behavior, ensure no breaking changes over releases.

Environment & Test Data Approach

- Use at least two environments: a staging (or test) environment with controlled data, and (if possible) production (or production-like) environment for smoke/regression tests.
- For test data: prepare a representative dataset covering wide variety.

Prioritization

- High Priority: Basic search and filter combinations.
- Medium Priority: Boundary value tests (min/max).
- Low Priority: Performance tests, negative tests for invalid input
